

SECTION 1

## Quasi-Geostrophic Equations

In this section, I introduce some basic equations in QG theories. Building a foundation for SQG, eSQG and other variations introduced later. The analysis is already in a **stratified ocean**.

SUBSECTION 1.1

### Governing Equations

Momentum Equation

$$\frac{D\mathbf{u}}{Dt} + \mathbf{f} \times \mathbf{u} = -\frac{\nabla p}{\rho} \quad (1.1)$$

Mass Conservation

$$\frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{v} = 0 \quad (1.2)$$

We are in a **stratified ocean**. Breaking the total state variables into a "hydrostatic reference state" (which depends only on  $z$ ) and a "dynamic perturbation" (which moves the fluid):

$$\rho = \tilde{\rho}(z) + \rho_1(x, y, z, t) \quad (1.3)$$

and

$$p = p_0(z) + p_1(x, y, z, t) \quad (1.4)$$

Then RHS of Eq 1.6 becomes

$$-\frac{1}{\rho} \nabla p_1 \sim -\frac{1}{\rho_0} \nabla p_1$$

Define the **Kinematic Pressure**

$$\phi = \frac{p_1}{\rho_0} \quad (1.5)$$

Momentum Equation becomes

$$\boxed{\frac{D\mathbf{u}}{Dt} + \mathbf{f} \times \mathbf{u} = -\nabla \phi} \quad (1.6)$$

Hydrostatic balance is a state of equilibrium in a fluid where the upward force of pressure exactly balances the downward force of gravity.

$$-g\tilde{\rho} = \frac{dp_0}{dz} \quad (1.7)$$

#### 1.1.1 Continuity Equation Approximation

The general continuity equation can always be expressed as

$$\frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{u} = 0$$

In Ocean, we assume that the fluid is **Incompressible** and wrote

$$\frac{D\rho}{Dt} = 0 \quad \nabla \cdot \mathbf{u} = 0$$

In Atmosphere, we use the **Anelastic Assumption** Then the mass conservation yeilds

$$\frac{\partial \rho_1}{\partial t} + \nabla \cdot ((\tilde{\rho} + \rho_1)\mathbf{v}) = 0 \quad \Rightarrow \quad \boxed{\nabla \cdot (\tilde{\rho}\mathbf{v}) = 0}$$

Remark 1

Here we drop the  $\partial_t \rho_1$  term under the **Anelastic assumption**. Essentially by eliminating this partial derivative, we assume the fluid is anelastic, so sound wave is not supported<sup>1</sup> in the system. However, this approximation is normally used for **deep atmospheric or stellar convection** where density  $\tilde{\rho}$  changes significantly with height.

For Oceanography, Next we define the Buoyancy :

$$b = -g \frac{\rho}{\bar{\rho}_0} \quad (1.8)$$

Here  $\bar{\rho}_0$  is a constant reference density. The the divergent free condition implies

$$\boxed{\frac{Db}{Dt} = 0} \quad (1.9)$$

And thus the Hydrostatic balance equation Eq 1.7 implies

$$\boxed{\frac{\partial \phi}{\partial z} = b} \quad (1.10)$$

All the Boxed Equation together is the **Hydrostatic Anelastic Equations for Stratified Flow**.

If we consider the perturbation of Buoyancy

$$b = \tilde{b}(z) + b_1(x, y, z, t)$$

Expand Eq 1.9 can be writen as

$$\boxed{\frac{Db_1}{Dt} + w \frac{db}{dz} = 0}^2 \quad (1.11)$$

In a more familiar form we define

$$N^2 = \frac{db}{dz} = -g \frac{\bar{\rho}_z}{\bar{\rho}_0}$$

Which is the **Brunt Vasala Frequency**.

#### SUBSECTION 1.2

### Scaling Analysis

To simplify our equation, we introduce some scalings.

$$(x, y) \sim L, \quad (u, v) \sim U, \quad t \sim \frac{L}{U}, \quad z \sim H, \quad f \sim f_0$$

Introduce the **Rosbby Number**:

$$Ro = \frac{U}{f_0 L} \quad (1.12)$$

Now let  $\phi = \tilde{\phi}(z) + \phi_1(x, y, z, t)$ . Then since the gradient in Eq 1.6 is horizontal, we can replace  $\phi$  by  $\phi_1$ . Now suppose

$$|\mathbf{f} \times \mathbf{u}| \sim |\nabla \phi_1|$$

From Hydrostatic balance we have

$$b \sim \frac{f_0 UL}{H}$$

Then

$$\frac{(\partial b' / \partial z)}{N^2} \sim \frac{f_0 UL}{(HN)^2} \sim Ro \frac{L^2}{L_d^2}$$

Where we have the deformation radius as a function of  $z$ .

$$L_d = \frac{NH}{f_0}$$

Introduce dimensionless variables

$$(\hat{u}, \hat{v}) = U^{-1}(u, v) \quad \hat{w} = \frac{L}{UH}w, \quad \hat{f} = f_0^{-1}f, \quad \hat{\phi} = \frac{\phi_1}{f_0 UL}, \quad \hat{b} = \frac{H}{f_0 UL}b_1$$

**Remark 2**

We then have dimensionless equation of motion for Atmosphere or Ocean.<sup>3</sup>

$$\text{Momentum Equation : } Ro \frac{D\hat{\mathbf{u}}}{Dt} + \hat{\mathbf{f}} \times \hat{\mathbf{u}} = -\nabla \hat{\phi} \quad (1.13)$$

$$\text{Buoyancy Equation : } Ro \frac{D\hat{b}}{Dt} + \left(\frac{L_d}{L}\right)^2 \hat{w} = 0 \quad (1.14)$$

$$\text{Hydrostatic Balance : } \frac{\partial \hat{\phi}}{\partial \hat{z}} = \hat{b} \quad (1.15)$$

$$\text{Continuity(Atmosphere) : } \hat{\nabla} \cdot \hat{\mathbf{u}} + \frac{1}{\hat{\rho}} \frac{\partial \hat{\rho} \hat{w}}{\partial \hat{z}} = 0 \quad (1.16)$$

$$\text{Continuity(Oceanography) : } \hat{\nabla} \cdot \hat{\mathbf{u}} = 0 \quad (1.17)$$

From now on I will drop the hats.

<sup>3</sup>often people drop the hat for simplicity. However in the first derivation I keep everything with a hat.

### SUBSECTION 1.3

## Quasi-Geostrophic Potential Vorticity Equation

We now derive the Quasi-Geostrophic Potential Vorticity Equations. Starting from asymptotic expansions<sup>4</sup>

$$\mathbf{u} = (u, v, w) = \mathbf{u}_g + Ro \mathbf{u}_1 \quad \phi = \phi_0 + Ro \phi_1 \quad b = b_0 + Ro b_1$$

Here we consider the  $\beta$  effect.

$$\mathbf{f} = f_0 \mathbf{k} + \beta y \mathbf{k}$$

Let  $\epsilon = Ro$ . **Momentum Equation :**

The  $O(1)$  momentum equation gives the Geostrophic balance

$$f_0 \mathbf{k} \times \mathbf{u}_g = -\nabla \phi_0 \quad (1.18)$$

Immediately this implies

$$\nabla \cdot \mathbf{u}_g = 0$$

And  $O(\epsilon)$  is

$$\frac{D_g \mathbf{u}_g}{Dt} + \beta y \mathbf{k} \times \mathbf{u}_g + f_0 \mathbf{k} \times \mathbf{u}_1 = -\nabla \phi_1 \quad (1.19)$$

<sup>4</sup>hat is dropped

Here  $D_g$  is the geostrophic material derivative

$$D_g = \partial_t + \mathbf{u}_g \cdot \nabla$$

**Mass Equation :**

Since geostrophic velocity is divergent free then  $O(1)$  mass equations is

$$\frac{\partial \tilde{\rho} w_0}{\partial z} = 0$$

and  $O(\epsilon)$ ,

$$\nabla \cdot \mathbf{u}_1 + \frac{1}{\tilde{\rho}} \left( \frac{\partial \tilde{\rho} w_1}{\partial z} \right) = 0 \quad (1.20)$$

**Buoyancy Equation :**

$O(1)$  :

$$\left( \frac{L_d}{L} \right)^2 w_0 = 0$$

and  $O(\epsilon)$ :

$$\frac{D_g b_0}{Dt} + \left( \frac{L_d}{L} \right)^2 w_1 = 0 \quad (1.21)$$

Now we take the **Curl** of Eq 1.19, note that

$$\nabla \times (\mathbf{k} \times \mathbf{u}_1) = \mathbf{k} \nabla \cdot \mathbf{u}_1 - \underbrace{u_1 \nabla \cdot \mathbf{k}}_{=0} + \underbrace{(\mathbf{u}_1 \cdot \nabla) \mathbf{k}}_{=0} - \underbrace{(\mathbf{k} \cdot \nabla) \mathbf{u}_1}_{=0} = \mathbf{k} \nabla \cdot \mathbf{u}_1$$

Define the geostrophic vorticity :

$$\tilde{\zeta}_g = \nabla \times \mathbf{u}_g$$

Then Eq 1.19 becomes

$$\frac{D_g \tilde{\zeta}_g}{Dt} + \beta v_0 = -f_0 \nabla \cdot \mathbf{u}_1^5$$

<sup>5</sup>this equation is already in  $\mathbf{k}$  direction so the unit vector is dropped

Plug in Eq 1.20,

$$= \frac{f_0}{\tilde{\rho}} \frac{\partial \tilde{\rho} w_1}{\partial z}$$

Plug in Eq 1.21 to replace  $w_1$

$$= -\frac{f_0}{\tilde{\rho}} \frac{\partial}{\partial z} \underbrace{\left( \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \frac{D_g b_0}{Dt} \right)}_{\equiv I}$$

Now we examine  $I$ , normally in QG theory, we assume  $L_d$  is a constant. Thought from its definition,  $N$  could actually depends on  $z$ . Since  $\nabla \tilde{\rho} = 0$ , we can put the first two terms into the material derivative.<sup>6</sup>

<sup>6</sup>Here we use the  $f_0$  constant

$$I = \partial_z \left( \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \right) \frac{D_g b_0}{Dt} + \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \partial_z \frac{D_g b_0}{Dt} \equiv I_1 + I_2$$

Let's go back to the Hydrostatic balance equation,<sup>7</sup> For  $O(1)$ :

<sup>7</sup>we haven't use it yet.

$$\frac{\partial \phi_0}{\partial z} = b_0 \quad + \quad f_0 \mathbf{k} \times \mathbf{u}_g = -\nabla \phi_0 \quad \Rightarrow \quad \mathbf{k} \times \frac{\partial \mathbf{u}_g}{\partial z} = -\frac{\nabla b_0}{f_0}$$

Then

$$I_2 = \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \partial_z \frac{D_g b_0}{Dt} = \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \left[ \frac{D_g \partial_z b_0}{Dt} + \underbrace{\partial_z \mathbf{u}_g \cdot \nabla b_0}_{=0} \right]$$

Therefore

$$I = \partial_z \left( \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \right) \frac{D_g b_0}{Dt} + \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \frac{D_g \partial_z b_0}{Dt} = \frac{D_g}{Dt} \left[ \partial_z \left( \tilde{\rho} \left( \frac{L}{L_d} \right)^2 b_0 \right) \right]$$

Then eventually we have

$$\frac{D_g}{Dt} \left[ \zeta_g + f + \frac{f_0}{\tilde{\rho}} \frac{\partial}{\partial z} \left( \tilde{\rho} \left( \frac{L}{L_d} \right)^2 b_0 \right) \right] = 0 \quad (1.22)$$

We can rewrite this equation using Streamfunction in a more simple form. Recall Eq 1.9, we have

$$b_0 = \frac{\partial \phi_0}{\partial z}$$

From Eq 1.18, the Kinematic Pressure can be expressed in terms of geostrophic streamfunction

$$u_g = -\partial_y \psi_g \quad v_g = \partial_x \psi_g \quad \text{where} \quad \boxed{\phi_0 = f_0 \psi_g} \quad \Rightarrow \quad \zeta_g = \nabla^2 \psi_g$$

Then Eq 1.22 becomes

$$\frac{D_g}{Dt} \left[ \nabla^2 \psi_g + f + \frac{f_0^2}{\tilde{\rho}} \frac{\partial}{\partial z} \left( \tilde{\rho} \left( \frac{L}{L_d} \right)^2 \frac{\partial \psi_g}{\partial z} \right) \right] = 0 \quad (1.23)$$

Restore the dimensions

$$\frac{D_g}{Dt} \left[ \nabla^2 \psi_g + f + \frac{f_0^2}{\tilde{\rho}} \frac{\partial}{\partial z} \left( \frac{\tilde{\rho}}{N^2} \frac{\partial \psi}{\partial z} \right) \right] = 0 \quad (1.24)$$

SUBSECTION 1.4

## Ertel PV Conservation

---

**Theorem 1.1** The Ertel PV, denoted usually as  $q$  or  $Q$ , is defined as:

$$Q = \frac{\boldsymbol{\omega}_a \cdot \nabla \psi}{\rho} \quad (1.25)$$

Where:

1.  $\boldsymbol{\omega}_a = \nabla \times \mathbf{u} + 2\boldsymbol{\Omega}$  is the absolute vorticity.
2.  $\psi$  is a conserved scalar (like potential temperature  $\theta$  or density).
3.  $\rho$  is the density.

The derivation starts from the Momentum Equation

$$\frac{D\mathbf{u}}{Dt} + \frac{1}{\rho} \nabla p = -2\boldsymbol{\Omega} \times \mathbf{u}$$

Use the vector identity then take Curl

$$(\mathbf{u} \cdot \nabla) \mathbf{u} = \nabla \left( \frac{1}{2} \mathbf{u}^2 \right) - \mathbf{u} \times (\nabla \times \mathbf{u})$$

We have

$$\frac{\partial \boldsymbol{\omega}_a}{\partial t} - \nabla \times (\mathbf{u} \times \boldsymbol{\omega}_a) = \nabla \times \left( -\frac{1}{\rho} \nabla p \right)$$

Then apply the vector identity

$$\nabla \times \left( \frac{1}{\rho} \nabla p \right) = \frac{1}{\rho^2} \nabla \rho \times \nabla p$$

We get

$$\frac{D\boldsymbol{\omega}_a}{Dt} = (\boldsymbol{\omega}_a \cdot \nabla) \mathbf{u} - \boldsymbol{\omega}_a (\nabla \cdot \mathbf{u}) + \frac{\nabla \rho \times \nabla p}{\rho^2} \quad (1.26)$$

## SECTION 2

# Surface Quasi-Geostrophic Equations

The surface Quasi-Geostrophic Equation takes the problem to the next step, how could we retrieve the interior motion from surface measurements such as SSH and SST. Recall the Buoyancy Equation

$$\frac{Db_1}{Dt} + wN^2 = 0 \quad (2.1)$$

At the surface,  $z = \eta$ , the boundary condition yields that  $w = 0$ . We denote the surface buoyancy as  $b_s$  and surface velocity  $\mathbf{u}_s$ . Then

$$\frac{\partial b_s}{\partial t} + \mathbf{u}_s \cdot \nabla b_s = 0$$

and

$$b_s = f_0 \frac{\partial \psi}{\partial z} \Big|_{z=0}$$

**Explanation 1** | The critical principle of SQG is to view surface buoyancy as a PV sheet. Since

$$\int_0^\epsilon f + \nabla^2 \psi_g + \frac{f_0^2}{\bar{\rho}} \frac{\partial}{\partial z} \left( \frac{\bar{\rho}}{N^2} \frac{\partial \psi}{\partial z} \right) dz = 0$$

Then we impose a boundary condition

$$\frac{\partial \psi}{\partial z} \Big|_{z=\epsilon} = \frac{b_s}{f_0} \Rightarrow \int_0^\epsilon \frac{b_s}{f_0} = \frac{\partial \psi}{\partial z} \Big|_0^\epsilon$$

Compare the latter with the integral, by defining

$$q_{\text{SQG}} = \nabla^2 \psi_g + f + \frac{f_0^2}{\bar{\rho}} \frac{\partial}{\partial z} \left( \frac{\bar{\rho}}{N^2} \frac{\partial \psi}{\partial z} \right) + \frac{b_s}{f_0} \delta(z)$$

We have

$$\frac{Dq}{Dt} = 0 \quad \frac{\partial \psi}{\partial z} = 0$$

Then the surface buoyancy appears in the QGPV equation naturally, it is as if adding an additional PV sheet at the surface. This inspires us to separate the surface induced dynamics and interior dynamics.

### Interior Dynamics

$$\begin{cases} q &= \nabla^2 \psi + f + \frac{f_0^2}{\bar{\rho}} \frac{\partial}{\partial z} \left( \frac{\bar{\rho}}{N^2} \frac{\partial \psi}{\partial z} \right) \\ f_0 \frac{\partial \psi}{\partial z} \Big|_{z=0} &= 0 \\ \frac{Dq}{Dt} &= 0 \end{cases}$$

#### SUBSECTION 2.1

### Surface Buoyancy Induced Dynamics

**Surface Dynamics**, this is the Surface Quasi-Geostrophic Dynamics:

$$\begin{cases} q &= \nabla^2 \psi + f + \frac{f_0^2}{\bar{\rho}} \frac{\partial}{\partial z} \left( \frac{\bar{\rho}}{N^2} \frac{\partial \psi}{\partial z} \right) = 0^8 \\ f_0 \frac{\partial \psi}{\partial z} \Big|_{z=0} &= b_s \\ \frac{Db_s}{Dt} &= 0 \end{cases}$$

The key assumption for SQG theories is that all the Potential vorticity is injected into the system by surface buoyancy.<sup>9</sup>

#### SUBSECTION 2.2

### Retrieving Vertical Velocity

## SECTION 3

QG<sup>+</sup>1 Model

The derivation starts from the same set of equations above. We set

$$\epsilon = \text{Ro} = \frac{U}{fL} \quad \text{Bu} = \left( \frac{NH}{fL} \right)^2$$

The Derivation starts from Eq 1.14, 1.17, 1.15 and 1.13. The **Ertel Potential Vorticity** is conserved. In this case, the conserved quantity is the **total Buoyancy** since Eq 1.14 we define it as

$$b_{\text{tot}} = N^2 z + b$$

and

$$\omega_a = \nabla_3 \times (u, v, 0) + f\hat{z} = (-v_z, u_z, f + \xi)$$

Then

$$Q = \underbrace{fN^2}_{\text{Background}} + \underbrace{(N^2\xi + fb_z)}_{\text{Linear terms, QGPV}} + \underbrace{(\xi b_z - v_z b_x + u_z b_y)}_{\text{Nonlinear terms}} \quad (3.1)$$

and

$$q_{\text{QG}} = N^2\xi + fb_z$$

Use the vector identity

$$\nabla_3 \cdot (\omega b) = \omega \cdot \nabla_3 b + \underbrace{b(\nabla \cdot \omega)}_{=0, \omega = \nabla \times \cdot}$$

We note that

$$\xi b_z - v_z b_x + u_z b_y = \omega \cdot \nabla_3 b$$

where

$$\omega = (-v_z, u_z, \xi) = (-v_z, u_z, v_x - u_y)$$

Then after scaling analysis we have

$$Q = N^2 f + \epsilon q$$

where

$$q = N^2\xi + \frac{1}{\text{Bu}}fb_z + \frac{\epsilon}{\text{Bu}}\nabla_3 \cdot (\omega b) \quad (3.2)$$

The first two term is the calssical Quasi Geostrophic Potential Vorticity.

**Explanation 2** Since here  $N$  is constant and we assume the Boussinesq Equation, the third term in Eq 1.22 becomes,

$$\frac{f_0}{\rho} \frac{\partial b}{\partial z} \left( \frac{fL}{NH} \right)^2 \sim fb_z \frac{1}{\text{Bu}}$$

The only difference here is the third second order ageostrophic quadratic correction we normally ignore in classical QG theories.

## SUBSECTION 3.1

QG<sup>+</sup>1 Vector Field

In order to facilitate asymptotic approximation, the velocity field  $\mathbf{u}$  are written as the Curl of a vector field  $\mathbf{A}$ .<sup>10</sup> One convention is writing

$$\mathbf{A} = (-G, F, \Phi) \quad (3.3)$$

and

$$\begin{aligned} \mathbf{u} &= \nabla \times \mathbf{A} \\ u &= -\Phi_y - F_z \\ v &= \Phi_x - G_z \\ w &= F_x + G_y \end{aligned}$$

The Horizontal Vorticity in vector potential form is

$$\zeta = v_x - u_y = \Phi_{xx} - G_{zx} + \Phi_{yy} + F_{zy} = \nabla^2 \Phi + F_{zy} - G_{zx}$$

However, this  $\mathbf{A}$  isn't uniquely correspond to a velocity field. Since Gradient is Curl free,  $\mathbf{u}$  admits a gauge freedom in that the transformation

$$\mathbf{A} \rightarrow \mathbf{A} + \nabla_3 \Gamma$$

Left  $\mathbf{u}$  unchange. Now instead of assuming  $\mathbf{A}$  is divergent free.<sup>11</sup> We fix the buoyancy to <sup>11</sup>if  $\mathbf{A}$  is divergent free, then this is adding an additional information to the system and  $\mathbf{A}$  can be uniquely determined.

$$\nabla_3 \cdot \mathbf{A} = -G_x + F_y - \Phi_z \Rightarrow b = f\Phi_z + \text{Bu} \frac{N^2}{f} (G_x - F_y)$$

The advantage can be seen by calculating the QGPV Eq 3.2 (Dimensionless form) :

$$q_{\text{QG}} = N^2 \zeta + \frac{f}{\text{Bu}} b_z = N^2 (\Phi_{xx} + \Phi_{yy}) + \frac{f^2}{\text{Bu}} \Phi_{zz} = \mathcal{L} \Phi \quad (3.4)$$

Where

$$\mathcal{L} = N^2 \nabla^2 + \frac{f^2}{\text{Bu}} \partial_{zz} \quad (3.5)$$

Then  $\Phi$  is the only component related to the QGPV compare to dependence on all three component of velocity in the classical QGPV. When is the Buoyancy unchanged?

**Explanation 3** Suppose we add a gradient to the original Vector Potential

$$\mathbf{A} \rightarrow \mathbf{A} + \nabla_3 \Gamma$$

Then

$$G \rightarrow G - \Gamma_x \quad F \rightarrow F + \Gamma_y \rightarrow \Phi \rightarrow \Phi - \Gamma_z$$

And

$$b_{\text{new}} = \underbrace{\left[ f\Phi_z + \{ \text{Bu} \} \frac{N^2}{f} (G_x - F_y) \right]}_{b_{\text{origin}}} - \underbrace{\left[ f\Gamma_{zz} + \{ \text{Bu} \} \frac{N^2}{f} (\Gamma_{xx} + \Gamma_{yy}) \right]}_{b_{\text{change}}}$$

So in order to have  $b_{\text{new}} = b_{\text{origin}}$ . We have

$$b_{\text{change}} = f\Gamma_{zz} + \{ \text{Bu} \} \frac{N^2}{f} (\Gamma_{xx} + \Gamma_{yy}) = \boxed{\mathcal{L}(\Gamma) = 0} \quad (3.6)$$

Some Discussions

1. **In a triply-periodic domain :**

Eq 3.6 implies that  $\Gamma$  is constant in the domain.

2. **Rigid Lid and flat bottom :**

since  $w = 0$  at upper and lower boundary, we have

$$F_x + G_y = 0$$

SUBSECTION 3.2

## Evolution and Inversion Equations of QG<sup>+1</sup>

Assume

$$G^0 = F^0 = 0$$

and

$$\epsilon \ll 1 \quad \text{Bu} \sim O(1)$$

Then expand  $A$  asymptotically we have

$$u = -\Phi_y^0 - \epsilon(\Phi_y^1 + F_z^1) \quad (3.7a)$$

$$v = \Phi_x^0 + \epsilon(\Phi_x^1 - G_z^1) \quad (3.7b)$$

$$w = 0 + \epsilon(F_x^1 + G_y^1) \quad (3.7c)$$

$$b = f\Phi_z^0 + \epsilon f \left( \Phi_z^1 + \text{Bu} \frac{N^2}{f^2} (G_x^1 - F_y^1) \right) \quad (3.7d)$$

Evaluate Eq 3.2 we have up to  $O(\epsilon)$ .

$$\begin{aligned} q &= N^2(\nabla^2 \Phi^0 + \nabla^2 \Phi^1 - G_{zx}^1 + F_{zy}^1) + \frac{f^2}{\text{Bu}} \Phi_z^0 + \epsilon \frac{f^2}{\text{Bu}} \left( \Phi_z^1 + \text{Bu} \frac{N^2}{f^2} (G_x^1 - F_y^1) \right) \\ &+ \underbrace{\left[ -\Phi_{xz}^0, -\Phi_{yz}^0, \nabla^2 \Phi^0 \right]}_{\text{This is } \omega = (-v_z, u_z, \zeta)} \cdot \underbrace{\left[ f\Phi_{zx}^0, f\Phi_{zy}^0, f\Phi_{zz}^0 \right]}_{\text{this is } \nabla_3 b} \\ &= \boxed{\mathcal{L}(\Phi^0) + \epsilon \mathcal{L}(\Phi^1) + \epsilon \frac{f}{\text{Bu}} \left( -|\nabla \Phi_z^0|^2 + \Phi_{zz}^0 \nabla^2 \Phi^0 \right) + O(\epsilon^2)} \end{aligned} \quad (3.8)$$

The surface Buoyancy from

$$b^t = f\Phi_z^0 \Big|_{z=0} + f\Phi_z^1 \Big|_{z=0} + O(\epsilon^2) \quad (3.9a)$$

$$b^b = f\Phi_z^0 \Big|_{z=-H} + f\Phi_z^1 \Big|_{z=-H} + O(\epsilon^2) \quad (3.9b)$$

To complete the inversion, we need to relate ageostrophic vertical streamfunctions  $F^1$  and

$G^1$  to  $\Phi^0$ . We start with the first order primitive equations

$$\frac{Du}{Dt} - fv^1 = -p_x^1 \quad (3.10a)$$

$$\frac{Dv}{Dt} + fu^1 = -p_y^1 \quad (3.10b)$$

$$\frac{Db}{Dt} + \text{Bu}N^2w^1 = 0 \quad (3.10c)$$

$$p_z^1 = b^1 \quad (3.10d)$$

Take the difference of z-derivative of  $f$  times Eq 3.10b and x-derivative Eq 3.10c we derive

$$\mathcal{L}(F^1) = \frac{2f}{\text{Bu}} J(\Phi_z^0, \Phi_x^0) \quad (3.11)$$

and similarly

$$\mathcal{L}(G^1) = \frac{2f}{\text{Bu}} J(\Phi_z^0, \Phi_y^0) \quad (3.12)$$

#### SECTION 4

### SQG<sup>+1</sup> Model

From the Geostrophic Balance Equation we have

$$\nabla^2 p^0 = f\zeta^0$$

To obtain the next order balance equation, we use Eq 3.7d, 3.11 and 3.12.

$$\begin{aligned} \nabla^2 b^1 - f\zeta_z^1 &= f \left( \nabla^2 \Phi_z + \text{Bu} \frac{N^2}{f^2} \nabla^2 (G_x - F_y) \right) - f \nabla^2 \Phi_z - f \partial_{zz} (G_x - F_y) \\ &= \frac{\text{Bu}}{f} \mathcal{L}(G_x - F_y) \end{aligned} \quad (4.1)$$

(Here apply Eq 3.11 and Eq 3.12)

$$= 2\partial_z J(\Phi_x^0, \Phi_y^0)$$

Recall that  $p_z = b$  by definition then we have

$$\boxed{\nabla^2 p^1 - f\zeta^1 = 2J(\Phi_x^0, \Phi_y^0)} \quad (4.2)$$

This model captures the ageostrophic at first order and the term on the right hand side represents the **cyclogeostrophic correction**. In SQG, interior potential vorticity is 0. Then from Eq 3.8, since  $q^1 = 0$ . Then

$$\mathcal{L}(\Phi^1) = \frac{f}{\text{Bu}} \left( |\nabla \Phi_z^0|^2 - \Phi_{zz}^0 \nabla^2 \Phi^0 \right)$$

Using  $\mathcal{L}(\Phi^0) = 0$ . We have

$$\mathcal{L}(\Phi^1) = \frac{f}{N^2 \text{Bu}} \left( N^2 |\nabla \Phi_z^0|^2 + \frac{f^2}{\text{Bu}} \Phi_{zz}^0 \Phi_{zz}^0 \right) \quad (4.3)$$

Together with Eq 3.11, Eq 3.12 and boundary conditions.

$$\Phi_z^1 = F^1 = G^1 = 0 \quad \text{at } z = 0$$

Further we assume all potential vanish at infinity.

**Explanation 4** For this system, the goal is to know  $\Phi^1, G^1$  and  $F^1$ . We recall that first order potential  $G^0 = F^0 = 0$ . And  $\Phi^0$  can be obtain from geostrophic balance. This is a system of decoupled linear elliptic (Poisson) equations.

1. Decoupled: You can solve for  $\Phi^1, F^1$ , and  $G^1$  independently of each other.
2. Linear/Poisson: Each equation takes the form  $\mathcal{L}(\text{Potential}) = \text{Source Term}$ .
3. Dependence: The "Source Terms" on the right-hand side (RHS) are known quantities derived entirely from the zeroth-order solution  $\Phi^0$  (which is obtained from the observed SSH/buoyancy)

The inversion is carried on by decomposing potential into interior and surface part. The interior part satisfies the main equations but ignore the boundary condition. The surface part solves the homogeneous problem and but corrects the boundary conditions. For  $\Phi^1$ , we first notice that

$$\Phi_{int}^1 = \frac{f}{2N^2\text{Bu}} \Phi_z^0 \Phi_z^0$$

Is a solution to Eq 4.3. Then it remains to solve the surface part given by

$$\mathcal{L}(\Phi_{sur}^1) = 0 \tag{4.4}$$

$$\Phi_{sur,z}^{1,t} = C_b - \partial_z \Phi_{int,z}^{1,t} = C_b - \frac{f}{\text{Bu}N^2} \Phi_z^{0,t} \Phi_{zz}^{0,t} \tag{4.5}$$
